Notes:

- ***This list is not complete.*** See the pdf-manual (accessible via the "syntax" help file) for more.
- Squared brackets make a phrase optional.
- You can only specify up to ONE argument (but as many options as you like).
- Using "/" after "if", "in", "using" or "weight" changes how the information is stored in the local. For expressions, specify "=/exp" instead.
- You can name the options as you like (if it is local compatible), but the locals which store the input from an option are called the same as the option.
- With "integer" and "real", you can specify default values (this is what # stands for).
- Sometimes, it makes sense to specify "name" instead of "string": It only allows strings which could be used as names for objects such as matrices. In other words, only one element, no special characters etc. Plus, you can specify min & max.

Example

accepts no argument (there is nothing between syntax and the comma except for if/in/using)

allows the option **root** with an integer, otherwise takes the integer 2 as default, and stores the input in the local **`root`**

“in” optional, stores the phrase in local **`in`** **without** the word “in”

syntax [if] [in/], RUNning(varlist numeric) [root(integer 2)]

“if” optional, stores the phrase in local **`if`** **with** the word “if”

requires the option **running** (abbrev. **run**), but only with numeric variables, and stores the input in the local **`running`**
